Abstract of the Disclosure

A beauty care instrument, and in particular, a device for manicure, pedicure, and false nail applications which includes a fiberglass or Kevlar substrate with thicknesses ranging from .020 inches to .125 inches in which the flexibility is varied and a single layer of uniform diamond grit size is embedded on at least a surface of the substrate and the grit ranges from 30 to 1200 mesh.

My invention relates to beauty care instruments, and more particularly, to instruments relating to diamond abrasive techniques for manicure, pedicure, or false nail operations, that is, the maintenance of finger and toe nails and the skin of the hands and feet.

Nail files generally include a steel substrate on which particles of an abrasive material are retained by an adhesive. Diamond particles have  
10 been suggested as abrasive particles for nail files as described in U. S. Patent 2,308,624, Pouech, 1943. In the Pouech patent, the diamonds are retained on a metal substrate by means of a thermoplastic adhesive.

U. S. Patent 4,369,098, Van Roeyen, 1983, suggests that abrasive particles can be held on a steel strip substrate by electroplating a metal layer over the particles, leaving a thick coating in the valleys and a thin coating over the tips. Although the retention of the abrasive particles is enhanced by the  
20 latter procedure, the disadvantages of a file with the tips of the particles being covered by a thin coat of nickel that must be worn down is quite evident.

The use of steel strips as a substrate is also considered a disadvantage because it is difficult to obtain a sufficiently flexible file for certain manicure uses. Furthermore, steel or other metal substrates are susceptible to corrosion when these instruments are cleaned with sufficiently strong cleaning fluids.

30 It is noted that the cutting and grinding industry has developed sanding and grinding products that could have applications to instruments of the type mentioned above, such as files and other instruments for the manicure and pedicure field. For instance, flexible belts and disks have been developed on which diamond particles have been electroplated or brazed for sanding stone and other similar products. The

substrate suggested for such belts is made of fiberglass. The diamond particles may be brazed on the substrate leaving 70% of the diamond particles exposed. The brazing technique is described in U. S. Patents 3,894,673, Lowder et al, 1975, and 4,018,576, Lowder et al, 1977, both assigned to Abrasive Technology, Inc.

It is an aim of the present invention to provide diamond abrasive instruments for the beauty care industry, particularly manicure, pedicure, and false nail instruments that embody some of the techniques developed for the cutting and grinding industry.

It is a further aim of the present invention to provide beauty care instruments that will include a substrate made of a fiberglass material or A.B.S., P.V.C., polypropylene, polyimide film, Mylar, Nylon, carbon fiber, and Kevlar, having a suitable thickness in relation to the degree of flexibility that is desired in a particular application. The selection of the grit size will also be important in determining the use to which the instrument will be applied.

An instrument for beauty care in accordance with my invention comprises at least a blank substrate made of a material selected from A.B.S., P.V.C., Mylar, fiberglass, carbon fiber, Nylon, Kevlar, polypropylene, and a single layer of diamond particles of uniform grit selected for the required use of the instrument, the diamond particles being retained to the substrate at least on one portion thereof by nickel plating.

More particularly, the substrate is a flat strip of fiberglass material having a thickness which is directly related to the required flexibility of the blank and ranging between .020 and .125 inches, and the diamond particles are of a uniform grit between 30 to 1200 mesh.

Thus, an instrument for beauty care can be tailored to a particular use. For instance, a nail

file of great flexibility and fine grit can be provided for filing, sculpting, and shaping real or false finger or toe nails. On the other hand, an instrument for removing heavy corns and calluses would require a thicker substrate and diamonds of a coarser grit. In other words, it is merely necessary to vary the thickness of the substrate to vary the flexibility of the instrument. On the other hand, a thin substrate of fiberglass having a thickness of approximately .010  
10 inches might be placed on a relatively stiffer backing of plastics material.

Having thus generally described the nature of the invention, reference will now be made to the accompanying drawings, showing by way of illustration, a preferred embodiment thereof, and in which:

Fig. 1 is a perspective view of a nail file in accordance with the present invention;

Fig. 2 is a perspective view of a further embodiment of the present invention;

20 Fig. 3 is a perspective view of a still further embodiment of the present invention;

Fig. 4 is a cross-section taken through a portion of a detail shown in Fig. 1; and

Fig. 5 is a perspective view of a still further embodiment of the present invention.

Referring now to the drawings, Figs. 1 and 4 show a typical flexible nail file embodying the present invention. The file 10 is shown as having a substrate 12 with diamond particles 14 on the top surface 16 of  
30 the file 10. As can be seen, the file 10 is in the form of an elongated flat strip with diamond particles disposed on only one surface, namely, surface 16. The opposite surface 18, in this embodiment, is smooth. It is contemplated, however, that the surface 18 could have a layer of abrasive diamond particles possibly of a different grit.

In the present embodiment, the substrate 12 is a strip of fiberglass material, and the diamond particles 14 have been electroplated to the top surface thereof. A brazing technique described in U. S. Patents 3,894,673 and 4,018,576 could also be used but not on all substrates in view of the heat treatment required. Fiberglass and Kevlar could be suitable substrates for brazing. This brazing technique allows a chemical bond between the diamond particles and the  
10 substrate surface 16.

In the embodiment shown in Figs. 1 and 4, the file 10 has a substrate 12 which is of fiberglass with a thickness that is typically .020 inches. This provides great flexibility which is not available from the typical metal file. Diamond particles have been electroplated to the top surface in a single layer, and the grit size of the diamonds is 220 to 600 mesh based on U. S. standard screen mesh size. This would be equivalent to between 74 and 30 microns. Such a  
20 flexible, fine grit file would be suitable for filing, shaping, and sculpting real finger nails as well as false nails and toe nails.

In order to file toe nails and false nails as well as removing dry and rough skin on fingers, a less flexible file 10 would be required. A fiberglass substrate 12 has a thickness in the order of .030 inches, and the grit size of the diamonds would be between 100 and 120 mesh which is equivalent to 149 to 175 microns.

30 For different applications, different thicknesses of the file and diamond grit would apply. For instance, the embodiment shown in Fig. 2 includes a file 30 with a handle portion 32 and a head portion 34. The substrate 12 forms part of the head 34 while the top surface 16 is provided with the layer of diamond particles 14.

A further embodiment used for filing heavy corns and calluses on one's feet could have a thickness of .030 inches with a grit size for the diamonds at approximately 50 mesh.

The substrates with .030 inch thickness could qualify as being semi-flexible while a fiberglass substrate having a thickness of .059 inches could qualify as being relatively rigid.

In the embodiment shown in Fig. 3, the file 10 40 has a handle 42 and a head 44 with the substrate overlying the head 44. What appears on the head 44 is the top surface 16 of the fiberglass substrate 12. A layer of diamond particles 14 having a grit size of between 70 to 100 mesh has been electroplated on the substrate 12. Such a device could be used for removing dry skin on one's feet.

A further embodiment is shown in Fig. 5, wherein a hand-held pad 50 is illustrated having a foam core 52 and a molded substrate 54 surrounding the foam core. The top surface 16 of this pad 50 is provided with a layer of diamond abrasive particles 14. In this embodiment, a thickness of the substrate between the foam core and the top surface 16 would be approximately .050 inches. On the other hand, a thin substrate having a thickness of .010 inches could overlay a more rigid backing of plastics material. This hand-held pad 50 might be provided with different uniform layers, one layer at a time, having a grit of anywhere from 30 to 1200 depending on the utility of the pad.

30 The substrate can be made from any number of materials, including plastics such as P.V.C., A.B.S., polypropylene, polyimide film, Mylar (registered trademark), Nylon (registered trademark), composite materials such as fiberglass, G-10, carbon fiber, and carbon and boron. Textile materials made of Kevlar (registered trademark) could also be utilized. The advantage of these materials is to provide flexible and

2142949

- 6 -

semi-flexible strips which can be varied depending on the thickness which is selected and which can be molded to different shapes and sizes. Thus, a combination of different grit size and thicknesses of the substrate will permit any combination of diamond abrasive instrument for different uses in the beauty care industry, including manicure, pedicure, and false nail sectors.

The substrate will also remain hygienic,  
10 being washable with antiseptic and non-bacterial solutions without fear of corrosion.

The embodiments of the invention in which an exclusive property or privilege is claimed are defined as follows:

1. A beauty care instrument comprising at least a blank substrate made of material selected from P.V.C., A.B.S., polypropylene, Mylar, Nylon, fiberglass, carbon fiber, and Kevlar; wherein said blank substrate has a thickness related to the required flexibility of the blank and a single layer of diamond particles of uniform grit selected for the required use of the instrument, wherein the diamond particles are retained to the substrate on at least one portion thereof by electroplating of a material selected from nickel and nickel alloy.
2. A beauty care instrument as defined in claim 1, wherein the substrate is a flat strip of fiberglass material having a thickness of between .020 and .125 inches and the diamond particles are of uniform grit size between 30 and 1200 mesh.
3. A beauty care instrument as defined in claim 1, wherein the blank substrate is part of a pad having a handle and a head portion on which the substrate overlies a backing of relatively less flexible material.
4. A beauty care instrument as defined in claim 1, wherein the substrate is in the form of a hollow block having a central foam core and a top surface to which a single layer of diamond particles has been applied.
5. A beauty care instrument as defined in claims 3 or 4, wherein the substrate is made of a material selected from fiberglass and Kevlar and has a

2142949

- 8 -

thickness of between .020 and .125 inches and the diamond particles range between 30 to 1200 mesh.

6. A beauty care instrument as defined in claim 2, wherein the substrate has a thickness of .020 inches and a uniform grit of between 220 to 600 mesh.

7. A beauty care instrument as defined in claim 2, wherein the substrate is .030 inches thick and the diamond particles have a uniform size ranging from 120 mesh to 220 mesh.

8. A beauty care instrument as defined in claim 3, wherein the substrate has a thickness of .030 inches and the grit of the diamond particles is 50 mesh.

9. A beauty care instrument as defined in claim 4, wherein the substrate has a thickness of .059 inches and a grit size of uniform particle size ranging from 70 mesh to 100 mesh.
